

yet due to the higher number of takers.

Wrong impressions: Keeping in tune with the idea of failed marketing tactics, one other thing that went wrong with Plasma was a wrong impression that was made in the consumers' mind- that a Plasma TV was a power-guzzler. Yes, it's true that compared to many common models, a Plasma TV does consume more electricity but the difference is actually small enough to be negligible. However, that was certainly not the message that

the audiences received-something which alienated them from the technology and contributed to it falling out of vogue.

Weight: Once you hang a TV on the wall, its weight doesn't really matter. But weight did have a negative impact on Plasma TV. And it was the manufacturers rather than the consumers for whom weight of the product became significant. For it became evident that shipping costs were considerably less for LED and LCD models as compared to the Plasma ones- yet another reason for brands to shift their focus away from Plasma.

Screen size: The story of television technology has not just been about improved picture clarity but also larger screen size. And in the super large category, the prices could be kept reasonable for LEDs which was not the case with Plasma TVs. And at a time when 60 and 70-inch televisions are inching towards becoming the norm, Plasma falls out of the race.

WHAT IS BRIGHTNESS?

One of the most misunderstood picture quality parameters, brightness is the amount of energy (luminance) emitted by the light source if we go by the textbook definition. However, in the context of displays, this parameter augments or reduces the red, green, and blue components in order to fine tune the overall luminance. The prime purpose of this metric is to adjust the display luminance until the correct black level is achieved.

Eidophor

Technically speaking, Eidophor isn't a dying technology as much as a long gone one. And as a piece of technology first conceived way back in 1939, perhaps it's not surprising that it's not in vogue anymore. Simply put, Eidophor is a television projector technology that could produce huge theatre sized images. The idea originated in Zurich from the collective brains of Dr. Fritz Fischer and a few people in the Swiss Federal Institute of Technology.
