

incorporates these two ideas: it's a reflective technology with liquid crystals in the place of mirrors. The liquid crystals, in this case are applied on a reflective mirror substrate. The light is either reflected or blocked depending on whether the liquid crystals open or close, modulating the light and thereby producing an image.

Reason(s) why it's on the way out:

The case with LCoS is not so much a case of dying out than about not ever coming to life properly. The technology, though rather obscure is not new by any means. For you can trace back its development to the rear end of the 1990s. In fact, the global giant JVC has been shipping professional front projectors using this technology since 1998. The trouble though is that it's one technology that's extremely difficult to perfect. So much so that multiple companies have dropped out of creating the technology or even gone bankrupt because of it. The first commercial LCoS HDTV was created by Thomson, an act that was followed by other heavyweights like Toshiba and Philips. But the fact is that all of these companies ceased producing the technology by October 2004. Even Intel abandoned the idea of producing LCoS not too long after they announced their ambitious plan to get into the market with the technology in January 2004. Even though a second generation of LCoS began to be created in the mid-2000s by the likes of JVC and Sony and used in their HDTVs the technology still failed to make an impact, given how projection technologies became savvier in the following years with a rapidity that LCoS simply couldn't keep up with.

E-ink

If you haven't heard of E-Ink before, you are not alone. In fact, you are definitely a part of the majority. Because even before E-Ink had a chance to make waves, it's dying. And the more fascinating fact is that the technology was a recent invention to begin with.

E-ink or electronic ink was created by the firm unsurprisingly called E Ink. The technology is commonly called as "bistable" because the image on a E Ink screen would remain even if all sources of power were removed. The advantage of such a mechanism is that it reduces significantly the power consumption of displays. The E Ink displays are used in major e-readers including the Amazon Kindle and Barnes & Noble Nook. The display is good for reading in bright sunlight as well.
