

e-Ink

Reason(s) why it's on the way out:

So, what brought the E-ink technology to its knees? One can cite not one but two reasons, actually: the first being the invent of displays for traditional LCD surfaces that were equally good or maybe even better than what E-ink offers. The magic transforming displays from Pixel Qi is a case in point. Another-perhaps more significant reason for its downfall is the ever increasing popularity of tablets. Those who read tend to do so on their tablet, viewing dedicated e-readers an overhead. This obviously is bad news for E-ink for whom e-readers are their mainstay. And even though Amazon's Kindle is selling well, that's nearly not enough, or so it seems from the slipping financial returns the company, E Ink has been posting over the last few years.

Gyricon

Gyricon is a kind of e-paper that has a double sided plastic sheet which is quite transparent. Inside the sheet, however are millions of twin-coloured balls with a width of just 0.1 mm. Whenever exposed to electrical charge these balls are rotated and depending on the strength of the electric pulses they receive, the balls would display either black or white. Gyricon was developed at Xerox's famous Palo Alto Research Center(PARC).
