

degree or arcminutes per pixel. 60 pixels per degree or 1 arcminute/pixel is considered eye limiting resolution

**Binocular Overlap:** This is the basis for stereoscopic vision, and it allows sensing the difference between near and far. Humans have a overlap of about 100° degrees, half on each side of the nose.

The larger the overlap, the better

The larger the overlap, the greater the sense of depth. The overlap on HMDs is mentioned in degrees or as a percentage overlap

**On Board Processing:** HMDs that provide on-board processing, or allow a device to be used locally within the setup allow more freedom of movement during their usage.

**Dealing with VR sickness:** Although VR sickness is not something that everyone goes through, it is something significant enough to bring down a technology. A lot of specific techniques have been implemented by specific manufacturers and it is certainly worth it to have a look at which one feels the best.

**Latency:** Latency refers to the delay between your actual movement and its effect being visible on the head mounted display. Shorter the delay, less sickening the experience is. A high latency often leads to nausea and disorientation.

**Comfort :** Some HMDs come with additional casing and eye panels so that people with glasses or even kids can use them without solely having to rely on the head-strap of the device. Lens adjustment is also becoming popular to accommodate different vision corrections.
