

handle the extra load. As a thumb rule, Full HD resolution is good enough for TV usage. You don't want to get 4K TVs yet because there isn't any real 4K content and existing Full HD streaming and Blu-ray content will look worse on a non-native 4K screen.

Apart from the usual trappings of OLED and LCD, panels also come in glossy and matte choices. The glossy variants are come in handy if you are keen on maintaining blacks fidelity and prefer your colours popping out unhindered. On the down side, these panels tend to be extremely susceptible to glare and reflections. Modern glossy plasma panels compensate by employing high-tech anti-reflective and anti-glare coatings, though. Matte displays, on the other hand, may reduce glare and reflections, but an aggressive matte coating can affect sharpness and diminish the integrity of whites, as well as hinder black levels. It's wiser to opt for glossy displays if you have ideal lighting conditions and no instances of glare and reflections.

Going 3D

This matter is more subjective than objective, but with my personal preference being to avoid 3D like the plague. The reasons for this are abundant. For starters, there's a lack of substantial 3D content, and even when you do find 3D films, the quality isn't up to the mark. Important picture parameters such as sharpness, brightness, and colour accuracy suffer thanks to the rather convoluted nature of 3D display technology, because separate images need to be directed at each eye. Since this sort of stereoscopy is unnatural, the human brain perceives the relayed 3D image as an anomaly and actively tries to correct it. This is a major cause of headaches as a consequence. What's more, letting kids view 3D content can be detrimental. The brains of younger children are still adapting and learning, so it's a bad idea to confuse the same with 3D imaging, which is inherently disorienting and can potentially cause long-term spatial learning issues.

However, if you are still keen on taking a dive into the 3D realm, you have to focus on the two main 3D technologies. This includes passive 3D that employs polarised glasses and active LCD shutter technology, which tends to be more expensive and bulky. The former is relatively low tech, but tends to consistently deliver a more stable and fatigue-free 3D experience. LCD shutter technology, however, may exhibit flickering and cause more headaches despite being complicated and expensive as well. Nevertheless, a bad implementation of passive 3D tech will still pale against a good active
