Final Considerations

HDMI is the de facto standard and therefore you need at least three of those inputs at the bare minimum for your set-top box, DVD/Blu-ray player, and video game console. If you plan to hook up your PC as well, and it's perfectly alright to do so, you may want to check out the superior DVI-D, and in some rare cases, Display Port inputs as well. These are foolproof means to get signal from your PC because the DRM-addled nature of the HDMI standard means that certain TVs (those made by Panasonic, for example) will not let you hook up a PC through the HDMI interconnect.

Additional features such as digital audio outputs and TRS stereo/headphone outputs come in handy to get a clean digital audio signal out of the TV or to connect headphones. Most modern TVs ship with USB inputs, which allow playback of various video formats. This is a boon for those who want to watch photos or downloaded movies, but don't expect them to deliver the performance and the file support of standalone devices specifically meant for the purpose.
