

the contrast setting to optimum level. What you're looking for is the ability of the display maintain optimum contrast levels in order to distinguish between the last five swatches represented by the values 250 to 254. Make sure the contrast is set as high as possible without causing the swatches to bloom at the edges. A good display will be capable of displaying all five tints.

◆ **Contrast**

As the name suggests, this test measures the extent of contrast the television is capable of displaying and the overall uniformity. You're want to use this test image to fine tune the brightness and contrast settings until the display can distinguish between as many RGB values 1 to 5 (leftmost swatches) and 28 to 32 (rightmost swatches), while also maintaining the uniformity within the gradient.

◆ **Gradient Banding**

Before viewing this test image, make sure to check if your video card or display source itself is capable of displaying "true colour" depth (24 million colours) and isn't susceptible to banding artefacts. Thereafter, you will observe the TV for smooth transition from deep black to bright white. Displays that show discernible banding and greenish/pinkish discolouration in some swatches aren't capable of reproducing the entire colour spectrum. Either that or the source (GPU) cannot handle true colour modes. This test is more to identify and rectify anything that prevents your display from reproducing the full colour gamut than a means to tweak any display settings.

◆ **Sharpness**

This test image is best viewed from a fairly large distance. You're essentially adjusting the sharpness until the entire image appears grey from a distance. If the display cannot make the central circle disappear, it means the the gamma settings are off.

◆ **Gamma**

This test image is best viewed from a distance at which the horizontal stripes appear uniform. Now, observe the image to check exactly where the lighter and darker bands within the vertical colour bars blend into each other. The bands should ideally blend in at 2.25 (48%), 2.20 (25%), and 2.17 (10%) for the three vertical bars. If they don't adjust the gamma settings through the GPU, or if that setting is available on the display itself.
