

In case you still want to try your hand at setting up your own virtual machine on your PC/Linux OS, you'll need the following software to get started:

1. A PC running 64-bit Windows or a 64-bit Linux distribution with at least a dual-core processor and 4GB of RAM. Mountain Lion is 64-bit, and thus requires your copy of Windows to be 64-bit. In the case you have a 32-bit distribution of either, you can install Snow Leopard instead. To know whether you own a 32 or 64-bit system, go to the "About" section in your device through the Control Panel (for Windows) or by typing `uname -m` in the terminal, which will display whether your system is 32-bit ("i686" or "i386") or 64-bit ("x86_64"). Note that your processor also needs to support VT-x.

2. VirtualBox and the VirtualBox Extension Pack: Like mentioned earlier, VirtualBox is free, unlike VMware, and can be installed from the VirtualBox website. And even though it doesn't officially support OS X, it's actually very easy to get up and running. You should download the main program and the Extension Pack, which will give you support for USB devices.

3. A Mountain Lion distro: Sadly, this won't work with a vanilla Mountain Lion installer, so you'll have to find a compatible hacked version. The hacking group Olarila has put a great installation ISO together, and you can find it by searching on Google.

4. The HackBoot 1 and HackBoot 2 ISO files. These will help you boot into the installation.

The paid enrollment gives you more than just the ability to publish on App store
