

different placements and sizes for the text field. To create any kind of element on the storyboard, navigate to the object library that appears at the bottom right of the utility bar. A list should appear with names and descriptions of the objects you can insert. Click on the text field option.

Inserting the text field into the UI is so simple, it's almost like it's straight out of MS Paint. Easy click and drag options creates a text box of the size you want. The interface also lets you align the text box to a set of margins using anchors the same way that normal word processor or design software would. Clicking on the text box will reveal the resize handles, allowing you to rescale and resize the textbox if your needs change later on.

Once you're happy with the placement and size, select the Attributes column in the utility area. This gives you a whole set of options for you to modify the text box. Change the colour, size of style of the font and the placeholder text you want. You may also choose to modify the kind of keyboard that opens when one selects the textbox as well as spellchecking options.

Note that the textbox just created has no label or heading. Labels are viewed as separate objects in the object library which you can select in the same way that you selected the text box. Aligning it right above the textbox is simple using the anchors that are available.

So far, we have a textbox in which a user can insert some text, and a label to indicate the kind of text that has to go into the textbox. Let's now add some interactive elements by adding a button. In the object library select the button option. Drag and reposition it to wherever you need it. Customise it however you wish to. That simple.

Animating objects: A simple look at the possibilities

Static items get very boring very fast. To have some fun with our app, let's quickly try and write a bit of code to create an image that bounces around
