

the screen a few items. We create this in a separate app, but you can always add a plate of flying spaghetti to our existing food app if necessary.

1. Start with a new iPhone application. Title it whatever you need.
2. Next, create the interface. Open `Main.storyboard` and add an image view into the interface. Then add an image to that view.
3. Then create the image views outlet. Open `ViewController.swift` in the assistant. Control-drag from the image view to the view controller, and name the outlet `imageView`.
4. At this point, create a tap recognizer. Open `Main.storyboard` and drag in a Tap Gesture Recognizer. Open `ViewController.swift` in the assistant, Control-drag from the tap recognizer to the view controller, select Action from the menu, and name the action `tapped`.
5. Finally, implement the snapping dynamic. Replace `ViewController.swift` with the following code.

Code available at: <http://dgit.in/SafBooks>

Previewing the application

Previewing the interface periodically can ensure that your UI doesn't go awry as you keep adding layers to it. To preview your work, click the Assistant button in the toolbar and in the editor selection bar, switch assistant editor from automatic to `Preview > Main.storyboard(preview)`.

Putting all this together, you should get an app that has a menu text option with a flying picture of spaghetti bouncing around the screen. Nothing great, but pretty neat for a first attempt. The good thing about XCode and Swift is that further enhancements require fairly little coding as a lot of the functionality is inbuilt in terms of studio files. Creating bigger and more complicated apps is just a few clicks away on this great platform.

There are many online platforms that have dedicated tutorials that teach you how to get more complicated apps rolling on your devices. This article is only the starting point and hopefully a flying dish of spaghetti with a single text box gives you enough incentive to explore further. **d**
