

NSXMLParser

Obviously, in this day and age when we have a lot of pre-written libraries and classes there's no need to go about writing your own parser. For this application we are going to be using a class called NSXMLParser. It is a simple XML parser included in the iOS SDK that's commonly used for parsing XML feeds which can be then presented in the appealing manner we spoke of earlier. NSXMLParser parses XML feeds including the DTD declarations in an event-driven manner and then notifies its delegate regarding the different items – elements, attributes, CDATA blocks, author, date, comments, etc., – that it comes across as it goes through the feed. Manipulation of these items is not handled by the NSXMLParser class, that's our job.

Initialising a parser with the XML feed is done by simply referencing the URL as so.

- `convenience init?(contentsOfURL url: NSURL)`

NSURL is simply an object specifying the URL of the XML feed that we'll be parsing. You can also use:

- `init(data data: NSData)`

If the XML contents have been encapsulated in a data object or you can use

- `convenience init(stream stream: NSInputStream)`

If you want to parse the contents from a specified stream.

And we begin

Open your Xcode IDE and click on the File menu, navigate to New > Project. Or you can simply use the shortcut (Shift+Command+New) and
