

are left with an app that might as well be a simple wallpaper. Click on Next.

You'll then be presented a screen to choose options for your file like the Class name, programming language and Parent class. We put down DRTableViewCon- troller for the Class name and slotted it under UITableViewController as the parent (Subclass of).

The programming language is obviously Swift. The UITableViewController is an inbuilt class that creates a controller object using which we can manage the table view. Click on Next.

Now, locate DRTableViewCellController.swift class and add the NSXML- Parser class to it. All you have to do is link the NSXMLParserDelegate to this new class.

```
• class DRTableViewCellController: UITableViewController, NSXML-
  ParserDelegate{
```

Now we can use the functions listed under NSXMLParserDelegate to parse the XML feed in the app. However, we will need a new variable to use these functions. So let's go ahead and declare one.

```
• var dparser: NSXMLParser = NSXMLParser()
• Now add the following code right after it.
• override func viewDidLoad() {
• super.viewDidLoad()
• let url:NSURL = NSURL(string: "https://feeds.feedburner.
  com/digit/latest-news")
• dparser = NSXMLParser(contentsOfURL: url)
• dparser.delegate = self
• dparser.parse()
• }
```

We are overriding the viewDidLoad function and giving it the URL of the XML feed that we want to parse in the app which is <https://feeds.feedburner.com/digit/latest-news>

We've already gone through the structure of an XML feed earlier. And for the sake of simplicity, the first view or the master view will only have the 'title' and 'link' elements from the feed.
