

Now you need to link the `postLink` to ensure it opens up when the user taps on the said post. To do this add the following line.

- `var postLink: String = String()`

Finally, add the following lines of code under `viewDidLoad`. We are, essentially, calling `loadRequest` of the `UIWebView` when a user taps on the `PostLink`. This link is passed using the `NSURLRequest` object.

- `override func viewDidLoad() {`
- `super.viewDidLoad()`
- `let url: NSURL = NSURL(string: postLink)`
- `let request: NSURLRequest = NSURLRequest(URL: url)`
- `webView.loadRequest(request)`
- `webView.delegate = self`
- `}`

Now that we've done with all the linking, you need to ensure that the Activity Indicator View goes out of view when the page loads and comes back on when the page is loading in the background. To do this, add the following `UIWebView` delegate functions.

- `func webViewDidStartLoad(webView: UIWebView!) {`
- `activityIndicator.hidden = false`
- `activityIndicator.startAnimating()`
- `func webViewDidFinishLoad(webView: UIWebView!) {`
- `activityIndicator.hidden = true`
- `activityIndicator.stopAnimating()`

Now locate the Interface builder and connect the `webView` and `activityIndicator` to their controls in the `ViewController`. Use the connection inspector to do this. Finally, locate `DRTableViewController.swift` and add `prepareForSegue` function. Ensure that its identifier is 'viewpost'.

- `override func prepareForSegue(segue: UIStoryboardSegue!, sender: AnyObject!) {`
- `if segue.identifier == "viewpost" {`
- `let showArtt: ShowArt = showArts[tableView.indexPathForSelectedRow().row]`
- `let viewController = segue.destinationViewController as PostViewController`
- `viewController.postLink = showArt.postLink}}`

That's about it. You should now compile and run your project and then your first iOS app will be ready. Congratulations about that! Head on to the next chapter to learn how to test it. **d**
