

Since there are quite a few iOS devices around at any given time and due to the fact that API levels aren't the same across all devices since certain devices are not granted the latest iOS update or are missing some hardware element, there arises the need to develop for specific devices. Keeping this in mind you need to specify which device you are developing for.

Goto the Apple Developer website, login and navigate to Certificates, Identifiers & Profiles. To add a testing device, select the Devices tab under the iOS section. You can now add individual devices or a bunch of devices together. The latter option is for those who develop en masse and don't have the time and patience to manually add each and every single device. We're only bothered with the single device. Click on the (+) in the top right and add a new device. Give it a name and enter the UDID. To obtain the UDID of the device, simply fire up iTunes and navigate to the summary page. You should see your phone and its serial number. Click on the serial number and you'll see the UDID of the device.
