

Creating a Provisioning profile

A provisioning profile contains the information needed by the OS to check if the app is permitted to run on the device. So a provisioning profile is to be installed on each and every device. Head over to the Apple Developer web site and navigate to Certificates, Identifiers & Profiles section. Click on Provisioning Profiles under iOS Apps and click on the (+) in the top right corner. Select iOS App Development and then click continue.

Pick the App ID you've just created and click on continue again.

The steps forward are pretty simple, select the development certificate and associate it with the correct certificate. Then select all the devices that the provisioning profile needs to be installed on and proceed. Only these selected device will be able to run your apps. Generate your provisioning profile and download it to your machine. Double-click on the provisioning profile to automatically add it to Xcode.
