

Click “Generate New Token”, and put in your password to confirm the creation. The site will spew out a bunch of options for the level of access the token has. You shouldn’t have to change any of the options, because the defaults work just fine, for XCode. Just enter a title for your new token, and click on “Generate Token”. You’ll be presented with a token, once you do so. You’ll see the token only once, so copy it onto your clipboard right away.

Once in Xcode, select “Xcode” from the leftmost top menu, then select “preferences”. Click on the accounts tab, and you’ll be presented with a window asking for your username and password. Enter your GitHub username, but do NOT enter your GitHub password in the password field. Instead, enter the token you’ve just generated, in that field.

Once you’re done, close the preference pane, and click “Source Control” again. Click “Push”, and you’re done. You can now push repositories without having to generate new tokens every time. That’s all you have to do, to use GitHub with Xcode. **d**
