

For the purposes of this tutorial we're just going to focus on two portals. These are going to be used most frequently during your app development process. The iOS Provisioning Portal and iTunes Connect.

iOS Provisioning Center

Every app on the Apple App Store is required to have a signed Apple Certificate. This is required for the app to be able to run. If the signature on the certificate is missing or invalid, the app won't run.

Therefore as developers, we need to find a way to create and sign our own certificates. This is where the iOS Provisioning Center comes in. Over here you can create “profiles”. Profiles, otherwise called “code signing identities”, are files generated by the portal that allow Xcode to sign your apps up so that they identify as valid.

The Provisioning Portal can also generate push certificates for your apps, in case you want your app to send push notifications.

There are 2 types of profiles

Development profiles, which means the app will only work on specific device, and Distribution profiles, which is what is used to sign your app for the App Store. You need to wait for Apple's approval before these apps can be downloaded and installed.
