

Once downloaded you can open them and they'll show up on Xcode's organiser.

Now for the next step, you're going to test the app on your device. If you have an app that's ready to use, now is the time to bring that out.

Open the project in Xcode. Click on the project node of the tree, then click on target, and fill out the app version and deployment target through the project navigator.

Be careful when setting a deployment target, as this is what determines the minimum version of the code your iOS supports. So ensure that the code and version match or else your app will crash. The older the iOS version the better. For the purposes of this tutorial set it to 4.0.

Next you go to the "Info" tab and change the bundle identifier. This should be the same as the one you used for the App ID you registered previously.
