

the fictional depiction of the North Korean president's assassination. Seeing as how most fingers seemed to point towards North Korean government hackers, this incident could be classified as an act of cyber-terrorism between countries.

Ashley Madison

While most of the data leaked from these dumps is recoverable and might not cause damage to one's personal life, the fallout from the Ashley Madison dump in July 2015 was another story. Ashley Madison is a website caters to people who are already in relationships but still want to date. Hackers allegedly gained access to millions of the website's customer information database and posted 10 GB of personal data of users, including their names and email addresses. Since the website didn't ask for email verification for the profile to be created, many fake profiles were created. And since the company required the owner of the email account to pay money to delete the profile, many people with fake profiles or misunderstood names did not bother getting their accounts shut. All in all, many people ended up having their personal details exposed, when they had not intended for the same to happen.

LastPass

In another hack with slightly less devastating consequences, LastPass email addresses and encrypted master passwords were compromised in a breach in June 2015. Many password managers, such as LastPass, were created to address the issue that passwords are a notoriously poor form of security. They function by requiring you to remember one strong master
