Passwords

We all have passwords on our phones. A password can protect your privacy and keep all your important data private. Your phone stores passwords for various social accounts like Face book, Twitter, etc., and even more important stuff like passwords for your online wallets and internet banking portals. But the basic password system in almost all devices can bypassed, and all your personal information accessed. So here are some precautions you can take to make sure your phone and all your social accounts are 'hack safe'.

1. Not Saving passwords

It is as simple as it sounds. The next time a web page prompts you to store passwords, decline. Because your passwords can be stolen via simple phishing pages or even by accessing the cookies that the web page stores. Also, if you save passwords and if someone was to hack your phone or gain access to it, what's to stop them from using all your social security codes and payment passwords to make transactions? A lot of people have fallen prey to such malicious attacks and have been robbed online. It might seem a little paranoid to some, to those people I say, better safe than sorry.

2. Use Strong Passwords

Most of the websites that require you to save passwords will require you to have long alphanumeric passwords (at least 8-12 characters long). And it is a necessary practice. If you have simple passwords, they can be bypassed by social hackers or by using something as simple as permutations and combinations. A lot of people invest a lot of time in trying to figure out what people's passwords will be. So it is much safer and better to have a password that is not predictable such as your birth date or wedding anniversary or your maiden name. We can't stress upon how important it is to have a strong password.

3. Android built-in security

Android OS knows how important your security is for you, so it comes with a strong secure built in security system. You might have noticed that in the 'password' section of your settings, there are various types of passwords that you can use ranked according to how secure they are. The most commonly used password type is probably the linked dots password which can be very easily broken into. There is an option for keeping an alphanumeric
