

Saving yourself from the 'Bad guys'

The safest computer in the world is one that is turned off

Over the years Windows users have seen some of the nastiest viruses. From ransoms to irritating autorun viruses, we have seen it all. Security has never been Microsoft's strong suit but slowly and steadily it has built it up. Windows 10 is probably the most secure version till date.

But no computer in the world is unhackable. If you want to completely secure your windows machine, the best bet is to start afresh with a new installation. But if you don't want to lose all your installed software and saved data (which can be backed up anyways if you decide to do a fresh installation) follow these steps to scan and remove malware, and secure your PC:

- **Disconnect from the internet**

The first thing you need to do is disconnect your computer/ laptop from the internet. If your computer is hacked or infected with a virus/malware/spyware, disconnecting from the internet will stop it from communicating with the hacker.

To get away from the bad guys first get away from the internet
