

One main advantage that Linux brings to the table (or the desk, if you prefer it that way) is the better security that it offers. Sometimes, the case is such that an antivirus is more ornamentation than utilitarian. But that's not to say that Linux is an impenetrable fortress within which you can reside safely- a digital cocoon where you needn't fear any malicious element from entering. Such optimal scenarios are only possible in fantasies-possibly realized with CG made using computers that run on open source.

But there's no reason to fret. You are by no means a hapless damsel in distress. There are certain measures you can adopt to further secure your Linux system.

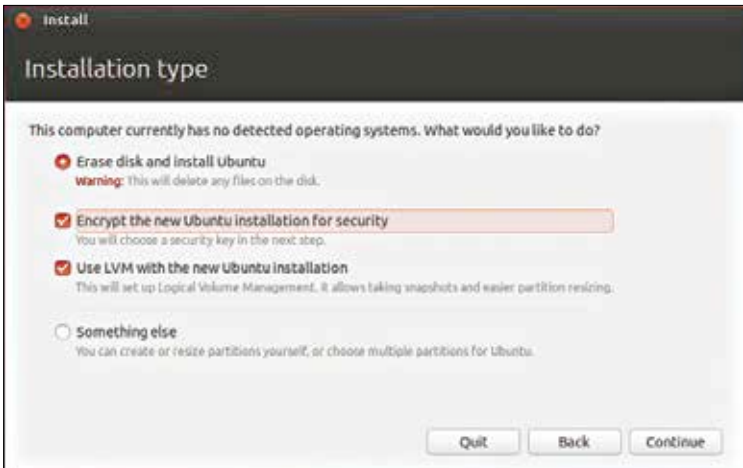

Let's start with looking at some basic tricks you can use:

Basic tips

Choose Full Disk Encryption

Regardless of the operating system that you use, it's always advisable to encrypt the entire hard disk. In the event that your laptop is lost or stolen, a login password won't probably be enough protection. For instance, one can easily boot into Linux from a USB key and read all the data on the system without using the password. By encrypting, it won't be possible to read anything without using the FDE password.

While encrypting only your home folder and the files contained in it is a possibility, FDE has a significant advantage - you won't have to worry

Go all the way, choose it fully!
