

Stay secure within the wall

This offers a pretty effective tool to manage network traffic and also to check different types of cyberattacks. In Ubuntu you will find the application called Uncomplicated Firewall(UFW) which is a frontend program which simplifies setting up iptables.

UFW would be disabled by default. To turn it on, you can bring up the command prompt and type the following on it:

- `$ sudo fw enable`

A graphical configuration tool like GUPFW or UFW Frontends could be a good tool to learn more about ipfire and more relevant - what it can do for you.

Fedora comes with the alternative firewall management toolkit called `firewalld`. It's enabled by default, so you can chill. A graphical user interface is also available for `firewalld`. Called `firewall-config`, you can install it from the command prompt using:

- `$ yum install firewall-config`

Improve browser security

It's important to have the browser secured as much as possible since the browser provides the way in for many contemporary cyber attacks. This is true whether you use Google Chrome, Mozilla Firefox, Opera or any other browser for that matter, so no point pointing the finger at any particular one.

However, to improve browser security- and your privacy, multiple free extensions are available. Some of the most effective options include
