Use an anti-virus software

Those who are super-confident of the security provisions that Linux naturally brings to the picture (and you'll be surprised by how many there are) may say

that an anti-virus on a Linux system is totally unwanted.

One reason why they say so is that most malware detected on a Linux system will be for Windows. But that doesn't mean that it's not a part of your problem. For instance, what if you pass a corrupted file to someone else.

And while it's a fact that malware on Linux desktops is rare compared to other systems, that still doesn't mean that they don't exist. It also doesn't mean that you are completely immune to attack. After all, rare doesn't mean zero.

Don't be anti anti-virus!

Most secure distros

Tails

One of the more widely recommended distros is Tails, and for good reasons. Tails is actually the short form for The Amnesic Incognito Live System. What makes Tails extremely recommendable is that it's user-friendly while having significant stress on security. Instead of just focusing on a secure OS, it also ensures that whatever you do on the system also remains secure—at least as much as possible from the get go.

Offers great stability and security

Tails is based on 's stable branch, so you can put your heart at ease since it's known for the great stability and security. Also, Tails runs in a live environment alone which is actually a smart security feature—given how it wipes out completely any trace of use on the

system once it's shut down or restart. Talk about being security conscious from the very beginning!
