

and fuse tools. GnuPG is also something you can use-it allows you to encrypt and sign data and communication and also has a versatile key management system and access modules for all types of public key directories.

Talk safely!

Use only the software that you actually want

We live in an age of choices-especially if you are a netizen. But that doesn't really mean that you need all those web services installed in the system, does it? If you don't install unnecessary software, you are by default bringing down the system's vulnerabilities. You can use an RPM package manager

Keep it simple, keep only those you want!

like yum to review the installed software packages on the system. That will give you a good idea of which packages are actually utilized and which are just taking up the space. Remove the latter.

Make a rule of running just one network service per system

It's always advisable to run different network services on separate servers. This is so that the number of other services which could be compromised can be limited. For instance, if a hacker successfully exploits a software
