

Install and make use of Intrusion Detection System

A Network intrusion detection system (NIDS) is a useful ally in your fight for better system protection. As the name makes it clear, the NIDS is a system that detects intrusions-more precisely malicious activities like denial of service attacks, port scans and attempts to breach into a computer by observing network traffic.

You will do good to deploy an integrity checking software before the system goes online. If at all possible, you should install AIDE software prior to the system getting connected to a network. For those who don't know, AIDE is actually a host-based intrusion detection system(HIDS) which could both monitor and analyze a computing system.

In the journey of securing your Linux system, the methods mentioned here will help you go a long way. And those who may wish to breach into your system will always fall short. **d**
