

Enable FileVault to secure your data

Make sure the bad guys don't know where you are

you can set up your system to ask you to enter your user account manually every time you boot or open your Mac.

Encrypting the entire hard disk

In the event that your Mac lies in the hands of thieves, a surefire way to protect your sensitive data is by having it encrypted from the start. Apple's FileVault is their proprietary software that encrypts all that you tell it to with the XTS-AES 128 algorithm. To turn it on head to System Preferences > Security and Privacy > FileVault and after unlatching the lock in the bottom left corner, click on Turn On FileVault. Your account will need to have a password which you will enter to unlock your hard drive everytime you start up

your Mac, which ties in to the previous point. However, in addition, every time you power down your Macintosh it will encrypt the entire hard disk making your precious data securely inaccessible to the prying penetrator.

Auditing your Security and Privacy settings

Under System Preferences > Security and Privacy > General, it is a good idea to set your computer to allow the installation of apps only from the App Store and Identified Developers. In the odd case that you need to install some software that doesn't have Apple's verified developer signature, you will be asked to enter your admin password to authorize the one-off case. This step greatly reduces your chances of being affected by rogue malware, unless you blindly accept every exception request of course.
