

TOR is the best bet to secure all your communication going in and out of your machine

is right now being developed by a non-profit organisation dedicated to developing online privacy tools.

How TOR works and why it is so secure, is because it encrypts your data and sends it through random nodes on the network to the destination. This makes sure that anyone who is monitoring the traffic cannot trace any data

back to its source or destination. To use TOR, follow these steps:

1. The easiest and quickest way to use TOR is to download the TOR browser for your operating system which is basically a modified version of Firefox with add ons and features that connect it directly to the TOR network.
2. Download and install the software from the project's official site only.
3. Open "start TOR Browser.exe" and a new window pops up asking if you want to connect directly to the internet over TOR or want to configure the settings.
4. Novice users should select 'Connect' directly instead of trying to configure the browser manually.
5. Check your IP address from both ,your normal browser and the TOR browser, by going to www.whatismyip.com. If the IP addresses displayed are both different then you are all set to go. Browse the internet anonymously.

• VPN

A VPN (or Virtual Private Network), tunnels your entire internet connection through a virtual local network. What this means is that all the data leaving your computer is encrypted and goes through a network of computers protecting your privacy from people trying to snoop on you. VPNs are a good choice if you are connected to the internet over some public Wi-Fi . There a number of free and paid VPN services out there which let are easy to download, install and use. Some of the good ones are:

1. OpenVPN server (free)
2. CyberGhost 5 (free)
3. Hotspot Shield (paid)
4. NordVPN (paid)
5. PureVPN (paid)
