

Stage monitor speakers

Many audiophiles prefer assembling their own speaker systems by hand, instead of purchasing a pre-made loudspeaker system that already holds all the drivers. Such level of customisation works well for home theatre systems, where the placement of speakers within the room can enhance (or ruin) your experience.

Other speaker classifications

The speakers we've seen till now work on the principle of electro dynamism i.e. the electromagnet is made to vibrate because of the presence of the magnetic field provided by the permanently fixed magnetic system. As electric current flows through the electromagnet, the magnetic field created by it reacts against the magnet's fixed field and moves the diaphragm back and forth.

Principle of operation:

There are speakers that operate on different principles – one of them is electrostatic speakers: sound is generated by the force exerted on a membrane suspended in an electrostatic field. The speakers employ the use of a thin diaphragm, usually a plastic sheet coated with a conductive material such as graphite, sandwiched between two electrically conductive grids. A small air gap is maintained between the diaphragm and grids. Seeing as how this
