

compensate for the small space available. Wireless headphones have an interesting architecture of electronics. Since there can't be wires running outside the headphones, everything is routed inside the headphones. The DAC and the batteries are distributed over the two ear cups, with wires running along the headbands to connect the two ear cups. Some wireless headphones, one of the first ones, used a different set up. There'd be a base station which connected through wires to the audio source and transmitted the signals wirelessly to the headphones. This usually happened through RF, which provided better sound quality and fewer instances of signal losses. This category is reserved exclusively for the professional audio technicians and sound recording studios who need the headphones to be perfect with very little latency which is difficult to achieve with Bluetooth headphones. These type of headphones can also be used in situations where the audio source cannot transmit the signals wirelessly on their own.

Truly wireless headphones/earphones are an emerging category, made popular by some crowdfunding campaigns. The argument here is that, Bluetooth earbuds or headphones are not truly wireless, because they use wires to tether the left and right ear piece together and deliver functionality through the inline remote and microphone. But this emerging category of truly wireless earphones means they are discrete; wherein even the left and right earbuds are connected wirelessly. These are the ultimate portability focused earbuds but the risk of spotty connectivity and loss of one earbud are extremely high.

Sport

Another category of wireless headphones are the ones used for sports. This category has become increasingly popular during the last few years owing to the convenience and the good sound quality. It can't really be clubbed into the connectivity sub-category since it's more of

Sport In ear Headphones provide a secure fit, while providing accurate sound and good battery life
