

a usecase-oriented classification, but we couldn't really put it anywhere else. This category of headphones puts a lot of focus on comfort and reliability and not a lot on the sound quality. When using these headphones with high intensity sports such as running, the Bluetooth earphones shouldn't fall off. They should also deliver good battery life and solid connectivity though bluetooth. The battery life on such earbuds can never be compared to those of on-ear or over-the-ear headphones as everything is reduced on these ear buds. The batteries are really really small, just enough to fit inside the ear. Another type of Bluetooth earphones which have emerged are being dubbed as neckbands. These have a contraption which go around the neck that carry the electronics and battery so that it takes some weight off the earbuds. These also tend to have better DACs and bigger batteries as they have more room for electronics. Bluetooth earphones with neckbands can also be used in a professional setting where there are multiple microphones which can be used for clearer audio when taking calls or recording audio.

Noise Reduction

Some headphones are specifically engineered to reduce the ambient sound and noise and dampen any outside noise. The removal or reduction of noise can be done by two methods, namely, noise isolation and noise cancellation.

Noise Isolation

Noise isolation is the process of delivering audio without much external noise or ambient sounds. This is done by tweaking the build of the headphones to reduce the amount of noise. By producing ear cups and cushions to better form a seal around the ear, most of the noise can be eliminated. Closed Back headphones help with noise isolation than open back headphones. Some OEMs even use drivers which are strategically placed or tuned to reduce the amount of noise entering the ear canal.

Active Noise Cancelling Headphones are usually expensive, but deliver results in noisy environments

Noise Cancellation

The real magic happens with noise cancel-
