

lation. Noise cancellation is the process of using sounds to cancel out the noise waves. More popularly known as active noise cancellation, some headphones use microphones placed in the ear cups to read the ambient noise and apply algorithms to generate waves to cancel the sound out. This works very well for dull persistent noises like the static noise of an airplane, train or general chatter, but can do little against people talking close by or cars honking. While noise cancellation is not perfect, it still achieves a decent amount of silence, even in busy environments.

Gaming Headphones come with multiple channels, providing virtual surround sound

Gaming Headphones

Gaming headsets can be given their own category, owing to the sheer engineering and innovation in this specific type of headphones. These headphones are worthy of using in professional gaming environments and often have more than one driver in the ear cups. Multiple drivers are used to form a directed sound, giving a broader sound stage. In most FPS games, the key is listening to the enemy's footsteps and gunshots, and headphones which cannot let you dwell upon the direction of the sound source may be counterproductive.

The size of the driver plays a crucial role in the sound quality
