

When home automation entered the market as a commercially viable field, it wasn't only the ease of control that started this trend. What also mattered was the necessity to control home appliances to increase energy efficiency.

In India, almost 25 per cent of India's energy consumption is through lighting, with heating and cooling appliances coming a close 2nd in energy consumption. This statistic only serves to prove that the future of sustainable lighting in India, and across the world, is through the usage of energy efficient lighting systems that make use of LED and CFL lighting that can be controlled remotely, to prevent wastage in scenarios such as when lights are left on needlessly, for extended periods of time, or when ambient lighting is available and not taken advantage of. Moreover, on a personal level, lighting constitutes 30 per cent of a household's electricity bill, and while measures like using CFLs and LEDs instead of incandescent bulbs might make a small difference, being able to control lighting remotely and setting certain schedules for it can bring down your electricity bill by as much as 30 per cent.

Smart lighting systems use a variety of techniques for implementation. You can choose any of these for your home, though budget and convenience will always be a constraint. It is more prudent and wise for people planning
