

Converting your house into a 'smart' house is a task that requires nerdiness, research and investment of both time and money

A smart HVAC just does all this 'smartly' and efficiently. This goes much farther than what a programmable thermostat can offer.

A smart HVAC not only controls and maintains the temperature of each and every room in your house, it automatically shuts off as soon as you leave your house, learns your habits and needs over time and automatically adjusts the temperature, saving you power and money, making your HVAC more efficient.

Generally, a smart HVAC is made up of a traditional HVAC system that is controlled via a thermostat (which have been around for some time). The traditional ventilation system, can also be replaced by smart vents that make the system even more intelligent and power efficient. There are several smart thermostats and vents from a variety of smart device vendors available in the market but none of them are cheap. So, before we take a look at them, some questions need to be answered: How do these systems work and should you upgrade to a smart HVAC?

How do smart HVAC systems work?

A smart HVAC system is constantly monitoring and learning from your actions. It comes equipped with many different sensors that record the number of people in the room, the temperature and humidity inside and outside, time of the day and much more. Then from this data over time, it 'learns' and adjusts the climate of your house automatically or lets you manually change it from the complimentary smartphone application.
