

desired results. With home automation the results that each user requires would be different, unlike, say in the case of a conventional TV monitor in which the only function is to stream images. This puts an extra demand on the software being flexible.

One software, multiple needs

Resilience:

Since home automation could involve the security control of a home, the software should be resilient-more than reasonably against threats that may result in it malfunctioning. The critical nature of some of the automation functions-like security or monitoring a baby's room means that there's a very low threshold of error in some cases. So, it's imperative that the software functions normally, almost without any room for error.

Types of home automation software

Open-source software:

Open source software refers to the type of software that is functional across multiple platforms and offers a high level of customizability. For instance, the software may well run on multiple operating systems while its interface could be designed as per your wish. This type of software is rarely immutable-which is the key to many an open-source software's popularity.
