

In this project, the Ultrasonic sensor placed at the top of the tank measures the level of water. When water level is low, distance between the sensor and water is maximum. When this happens, the water pump is switched on. When water level rises on pumping water, the distance between water and the ultrasonic sensor reduces, when water reaches the maximum level, the distance between sensor on top of tank and the water is minimum. When this condition is met, the water pump is stopped.

Uploading a sketch to an Arduino board
