

Angular 2 brings a lot of changes over Angular 1

only a specific Promise object will be injected. Another such annotation is the `@optional` annotation, using which an optional value or library can be injected.

An example of dependency injection is the following declaration:

- `constructor(messageList:MessageList) {`

A special application of dependency injection is *HTTP*. Using the *HttpClient*, which exist in the Angular/http package, a HTTP object can be injected. On this object, http operations can be performed. For the example, a public test server with a JSON response has been used. It can be called like this:

`http.get('http://jsonplaceholder.typicode.com/posts/1')`

Generics

Angular 2 uses TypeScript that supports generics which can be used in the frontend. Consider the below example which uses a Male and Female class that are both derived from Person. Both can prepare Food, however, the result is different. One only prepares raw food and the other can make delicious food.

- `export class Person {`
- `prepareFood(){return new Food("what to prepare?")}`
- `}`
- `export class Food(){`
- `typeOfFood:string`
- `constructor(typeOfFood:string){`
- `this.typeOfFood=typeOfFood`
- `}`
- `}`
- `export class Female extends Person{`
- `prepareFood(){return new Food("yummie")}`
- `}`
