

```

• export class Male extends Person{
•     prepareFood(){return new Food("raw")}
• }

```

In Angular, every class or directive that is used in a component that must first be imported in the component before it can actually be used. Here, the `ngFor` which was previously the `ng-repeat` directive has been imported to use all classes for the generics.

```

• @Component({
•     selector:'food-preparation'
• })
•
• @View({
•     templateUrl:'food.html',
•     directives:[NgFor]
• })
•
• class FoodPreparationComponent{
•     foods:Array<string>;
•
•     constructor(){
•         this.foods=[]
•         this.foods.push(prepareFood(new Male()));
•         this.foods.push(prepareFood(new Female()));
•     }
•
•     function prepareFood<T extends Person>(cooker:T):string{
•         return cooker.prepareFood().typeOfFood;
•     }
•
• bootstrap(FoodPreparationComponent);
• }

```

The “foods” list is now displayable with Angular, the following piece of HTML has been used:

```

• <p>Dishes:</p>
• <ul>
•     <li *ng-for="#food of foods">
•         {{ food }}
•     </li>
• </ul>

```

The browser then displays a list containing the strings “raw” and “yummie”.
