

Angular modules vs. JavaScript modules:

Angular Modules help organize an application properly into cohesive blocks of functionality. An Angular Module is a class with the `@NgModule` decorator function. `@NgModule` takes a metadata object that tells Angular how to compile and run module code. It identifies the module's own directives and pipes, components making some of them public so external components can use them. Service providers can be added to the appli-

A modular design ensures reusability of code

cation dependency injectors. JavaScript also has its own module system for managing collections of JavaScript objects. It's completely different and unrelated to the Angular module system. In JavaScript, each file is a module and all objects defined in the file belong to that module. The module declares some objects to be public by marking them with the `export` keyword. Other JavaScript modules use `import` statements to access public objects from other modules.

Directives

Directives are markers on a Document Object Model that tells Angular to attach a behaviour to that element. Directives with Angular 1 was quite complex to use. Angular 2 helps in passing data into the directives. They used to be the main way of creating custom tags in an Angular1 application. Now they have been replaced by Directives and Components.
