

```

• export class MyComponent {con-
  structor() {this.name = 'Digit'}
•   MyName() {      console.
    log('My name is', this.name)}}

```

New component is created called MyComponent, identified by tag <my-component>. By using @Component annotation we can specify a template for the component with the template property. When component is “instantiated”, we have an instance and we can modify instance data of the component, can be passed to other component or calls method on it. With Angular 2 components, we get a natural combination of all of these concepts: our Component has encapsulated instance data (much like isolate scopes), event handlers (much like methods attached to scopes), and a template (much like directives).

Introduction to Component Annotation

```

• @Component({
•   selector:'digit',
•   styles: [ require('\.digit.css') ],
•   template: require('\./digit.html),
•   directives: []
• })

```

Element Description	Annotation
What markup tag, element this component corresponds to. In this case the tag '<welcome></welcome>'.	selector
Specifies a css file for this component.	styles
Specifies a template file for this component.	template
Specifies that no directives are used by this component.	directives
If the template is a separate file, where it is located.	templateUrl
Pipes used by this Component's Template.	pipes
If the template uses one or more separate style files, where each one is located.	styleUrls
