

4.

- `FirstN:string;`
- `LastN:string;`

Instance variables in the Class (Model)

5.

- `constructor() {`
- `this.FirstN = 'Ron';`
- `this.LastN = 'Methew';`
- `}`

Constructs the Class and sets the instance variables.

6.

- `setName() {`
- `this.FirstN = 'Michael';`
- `this.LastN = 'Elango';`
- `}`

`setName` method sets the instance variable in the Class (Model). As these instance variable are part of Class, the View is updated.

## One Way Binding:

One Way binding uses double curly braces for binding a template expression, to compute from available data in the model and including it in the View. The expression generated a value and it is included in View but Model (Data in Class) is never repeated.

## Template Expression

Template expression is simple Js expression or can be defined as name of property in Class ( instance variable belonging to Component's Class). Angular replaces property name with the string value of instance variable. Angular can evaluate expressions ( method calls, property names etc) and converts the result into a string. After that is replaces the content and curly braces with the result.

Examples of curly braces and template expressions:

1. `{{1+getVal()}}`
2. `{{FirstN}}`
