

3. `{{FirstN}} {{LastN}}`

4. `{{2+2}}`

A longer example which shows the usage appropriately can be found at <http://dgit.in/TempExpEx>.

Templates

To define component's view template is used. A template is HTML that tells Angular how to render component. Two elements of the `@Component` annotation which can specify template:

- Template
- templateUrl

The first one is used to specify the template inline, the html markup is included right there in quotes. You can find the example for the same at <http://dgit.in/InTemp>. The second one is used to specify an external file, the filename is specified. You can find an example for that at <http://dgit.in/ExTempSpc> and the code you need to put into the external file is as below. File app.html

- ```
<div><h2>{{name}}</h2></div>
```

In a small project you can probably get away with inline template html markup. You can use external files on some of the more complicated html markups. In a large-scale project it is probably advisable to use external files for all templates for consistency. External files will keep your code easier to read and maintain once the template markup gets longer and more complicated.
