

- Helps to create forms dynamically.
- Validation of inputs from common validators.
- Validation of inputs from custom validators.
- Gives Test forms.

How to make a form in your component

1. Template:

Change the html form and input markup to use directives from the angular form module:

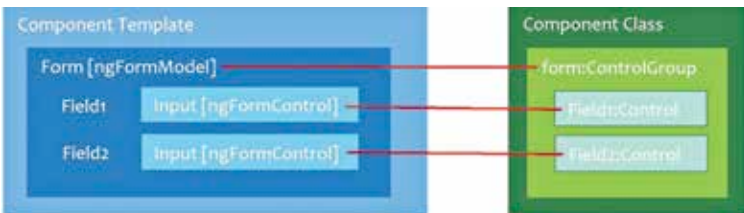

- 1.1. Amend the html form elements, to which you add the 'ngFormModel' directive. This directive binds the form to the FormGroup in the Class.
- 1.2. Amend the html input fields inside the html form, to which you add the 'ngFormControl' directive. This directive binds the field to a FormControl inside the FormGroup in the class.

2. Annotation:

Specify the form directives. Specify the css styles to highlight the form states (touched , untouched ,invalid, valid etc).

3. Class:

Constructor Injection is used to inject FormBuilder into the class. FormBuilder is used to create a Control Group, which represents a form, specifying the input fields and characteristics. Custom validations can be added with this.

Bindings in Angular 2

Styles

The Angular Form Module applies element styles to indicate their current state. To style your input fields to indicate their state, implement the follow styles as detailed below. The example code below uses the classes 'ng-valid' and 'ng-invalid'.
