

In most web applications, user navigates while performing application task from one page to the next. User can navigate by following links or clicking buttons or entering URL in address bar. In Angular2 applications, user can also navigates through the building-block of Angular2 applications. User can navigate to Component by following links or clicking buttons or entering URL in address bar.

Component Router

Angular2 Component router interpret a browser URL as an instruction to navigate to a component and pass parameters(containing information) to the Component to give it contextual information which helps it to decide what specific content to present. Router is binded to a link and it will navigate to appropriate Component when the user clicks a links or in response to some other stimulus from the source.

Nested routing

Nested Routing means the ability to route and navigate to Sub Components that are inside other Components which that are navigated to.

Routing Links DSL

Links can be specified in variety of formats using Router Link DSL. DSL is important in Angular because routes can get quite complicated , being absolute or relative inside nested components.

Configuration of Route Name

- `@RouteConfig([ * {path: '/customer', component: CustomerComponent, as: 'Customer'} *]);`

Router Link DSL Format

Use Route in a link by using the following Link DSL:

- `<a [routerLink]="['/Customer']">Customer</a>`

The format of the Link DSL is the following: `[prefix] [route names] [parameters]`

Prefix

The first route name should be prefixed with ``/``, ``./``, or ``../``. This indicates position or relativity.
