

Router Object

You can extract information out of the Router object that is injected into your class. For example, if you want to get the Route Name of your component you can use 'router.hostComponent.name'. You can also get the last navigation attempt by using 'router.lastNavigationAttempt'. Also the Router object passed into your class may have a parent Router. If you use 'router.parent' you will be able to get to this parent Router object.

RouteData object

RouteData is a class in the Angular2 Router module. It contains a data map you can configure in your Route and pass around using Constructor Injection. It's a great way of passing information about in an application.

Guards

Main task while building a application is to protect the routes, as we want to prevent our users from accessing are that the' are not allowed to access or can ask for confirmation when leaving a certain areas. This is handled by a feature known as Guard.

Types of Guards

- CanActivate - Decides if a route can be activated
- CanActivateChild - Decides if children routes of a route can be activated
- CanDeactivate - Decides if a route can be deactivated
- CanLoad - Decides if a module can be loaded lazily

Guards are registered using providers so they can be injected by Angular when needed.

Defining Guards as functions

```
• @NgModule({
•   ...
•   providers: [
•     provide: 'CanAlwaysActivateGuard',
•     useValue: () => {
•       return true;
•     }
•   ],
•   ...})
• export class AppModule {}
```
