

Services perform non-view related tasks

Now, traditionally an instance is created by the new keyword (new MyService()) and although this is not syntactically incorrect, it is highly recommended to not use this approach while using services in angular. Let us explore why.

Suppose we have a service MyService as defined above that is required in another component say FirstComponent as follows.

```
• import { Injectable } from '@angular/core';
• import { MyService } from './service';
export class FirstComponent{
• ngOnInit(){
• // need to call myService method here}}
```

If we declare the service with the new keyword then everything works! But wait.. What if you change the constructor signature of MyService at a later date? we would have to open and change all references (like in FirstComponent), of the old constructor for MyService in the entire application! A tedious and error prone task.

Thus this does not seem to be a very good way of using declared Angular2 services.
