

- Some text.
- `</div>`

Simple code to add multiple styles.

This directive expects a template expression that evaluates to an object containing style properties. This template expression can be in-line code like this:

- `[ngStyle]="{'color': 'blue', 'font-size': '24px', 'font-weight': 'bold'}"`

Or a function call like this:

- `[ngStyle]="setStyles(email)"`
- ... later on in the class ...
- `setStyles(email:String){`
- `let styles = {`
- `'width': '50px'`
- `} return styles;`

Explanation:

1. Directive can be used in this way.

- `<div *ngFor="#name of names">`
- `<div [ngStyle]="setStyles(name)"`
- `(click)="nameClicked($event)">{{name}}</div>`
- `</div>`

2. Alternate way of using directive

- `<template`
- `ngFor #name="$implicit"`
- `[ngForOf]="names">`
- `<div [ngStyle]="setStyles(name)"`
- `(click)="nameClicked($event)">{{name}}</div>`
- `</template>`

3. For list of names and selected names it creates instance variable, and they are bound to the html markup.

- `names:Any = ['digit1','digit2','digit3','digit4'];`
- `selectedname:String = 'digit1';`

4. This method is called on click event on the name. Sets the selected name instance variable bound to the template.
