

The Angular way forward

The popularity of JavaScript as a client side language is well known, it is perhaps one of the few languages that is considered the only go to option in its domain. However, traditionally JavaScript has been considered a lightweight language that does not do bulk of the heavy lifting, which was always a server's job. But we have also ignored that JavaScript is capable of blazing fast execution.

All of that has changed in the last few years, beautiful, rich applications have come up majorly client side with minimal interaction to a back-end server for data.

These applications have changed the browsing experience to more of an app-like feel. An interesting case study for this would be the newly launched Airbnb website which offers you the feel of a journey even before you have decided to undertake one. Such applications, still working on JavaScript soon realized that they needed to have a structure in the largely unstructured, loosely coupled language that JavaScript is. This led to the birth of several new frameworks that were built on top of it, as a means to improve structuring, code quality as well as maintainability of the application.

Multiple derived frameworks does bring to mind the need for a comparison, but trust us, the range is so wide and diverse that a fair comparison is, well, fairly impossible. And that's the beauty of it. Want a powerful View layer but don't need an elaborate framework for the rest of your application? Go with React. Need visualisation? Choose D3.js. Going 3D or building an interactive video game? Babylon.js is perfect for you. But when you are building a complex web front-end application and need a single modular framework to handle everything - Angular.js is the go to framework for that.

Although we aim to get you started from the very beginning, a little background in coding, especially in JavaScript, will be a great bonus on this journey to develop in Angular.js.

You can find an example project that builds a magazine subscription portal at <http://dgit.in/AngularProj>.
