

FILTERS IN DETAIL

Angular's data extraction tools are highly useful, and here's how to use them

Filters, as their name suggest are a way of extracting data from a larger set using certain operations. Although they can be used in a variety of ways, the most common use of filters is to format data. Filters are also a fantastic way of returning new collections of data, rather than mutating existing, which in some cases would be an issue if the collection is being shared across modules.
