

Pipe vs filter

Angular 1.X had a concept of filters. Pipes are very much similar to that but they have some significant advantages.

Filters used to act like helpers, very similar to functions where you pass the input and other parameters and that function returns you the value; but a pipe work more like a operator. The concept is, if you have an input , you can modify the input applying multiple pipes in it. This not only simplifies the nested pipe logic, but also gives you a beautiful and clean syntax for your templates. Secondly, in case of async operations, you need to set up things manually in case of angular 1.X filters. But pipes are smart enough to handle async operations.

Pipe and Filter class diagram

Usage of pipes

- You can display only some filtered elements from an array.
- You can modify or format a value.
- You can use them as a function.

General syntax

- `myValue | myPipe:param1:param2 | mySecondPipe:param1`

The pipe expression starts with the value to be operated on followed by the symbol pipe (`|`), then the pipe name. The params for that particular pipe can be sent separated by colon (`:`) symbol. However the pipe operator only works in our templates and not in JavaScript code. In JavaScript, the pipe symbol works as bitwise operator.
